

Lifestyle Inputs → Personalised Energy Estimate (Build Spec)

The idea in one line: the EPC gives a standard whole-home cost assuming *average* behaviour. We split that number into buckets, apply a multiplier per bucket based on how the user actually lives, and add it back up — giving a personalised range.

Honesty note (say this in the pitch): this makes the estimate *representative of how you'd live*, not precise to the pound. Behaviour is exactly what the EPC ignores — so this is us *closing the performance gap*, shown as a range that tightens as the user answers more.

Step 1 — Split the EPC total into end-use buckets

Take the EPC's estimated annual energy cost and split it (UK averages):

Bucket	Share of total	Driven by
Space heating	60%	thermostat, hours home, rooms heated
Hot water	18%	occupants, showers/baths
Appliances + lighting	17%	occupants, working from home
Cooking	5%	how often they cook

If the EPC record exposes separate heating / hot-water / lighting costs (RdSAP often does), use those directly instead of the percentages — more accurate, same logic.

Step 2 — The questions + their multipliers

Baseline 1.0 = the "average" assumption. Multipliers within a bucket multiply together.

How many people live here? (scales hot water, cooking, appliances)

Answer	Multiplier
1	0.70
2	1.00
3	1.25

Answer	Multiplier
4	1.45
5+	1.60

 **Where are you on weekdays? (→ *heating* ×, and *appliances* ×)**

Answer	Heating	Appliances
Mostly in an office	0.90	0.90
Hybrid	1.00	1.00
Work from home full-time	1.20	1.15

 **How warm do you keep your home? (→ *heating*)**

Answer	Multiplier
Cool (~18°C, jumper on)	0.82
Average (~20-21°C)	1.00
Warm (~22-23°C)	1.15

(Rule of thumb: ~~每~~1°C ≈ ~8% of heating.)

 **Do you heat the whole home, or just rooms you use? (→ *heating* — *this is the teammate's insight*)**

Answer	Multiplier
Whole home, evenly	1.00
Mainly the rooms I use	0.82
Just one or two rooms	0.65

🔧 Showers/baths per day (household)? (→ *hot water*)

Answer	Multiplier
Few (≈ 1)	0.75
Average (2-3)	1.00
Many (4+)	1.35

(A bath $\approx 2\times$ a shower's hot water — optional refinement.)

🔧 How often do you cook at home? (→ *cooking*)

Answer	Multiplier
Rarely (mostly eat out / takeaway)	0.50
Sometimes	1.00
Most days	1.40

Step 3 — Recombine

```
heating      = TOTAL × 0.60 × wfh_heat × thermostat × rooms_heated
hotwater     = TOTAL × 0.18 × household_size × shower_freq
appliances   = TOTAL × 0.17 × household_size × wfh_appliance
cooking      = TOTAL × 0.05 × household_size × cook_freq

personalised_total = heating + hotwater + appliances + cooking
```

Show it as a **range** ($\pm \sim 12\%$) rather than a single number — honest, and it demos beautifully as the range narrows with each answer.

Step 4 — The room / heat-map tie-in ★ (the teammate's point, made real)

Their insight: a home's heat isn't uniform, and people barely use the cold/awkward rooms — so a whole-home estimate over-counts. Here's how to make the heat map *feed the number* instead of just looking pretty:

Replace the single crude "rooms heated" multiplier with a **per-room** version, using the room tags you already collect:

```
heating = TOTAL × 0.60 × Σ (room_share × orientation_weight) // only over  
rooms marked "heated / used"
```

- Each room contributes a share of the heating load.
- `orientation_weight`: a north/exposed room loses more heat, so it counts **more** when heated (e.g. N $\approx$ 1.3, E/W $\approx$ 1.0, S $\approx$ 0.85).
- A room the user marks "**rarely used / don't heat**" drops out entirely → directly implements "don't charge me for the freezing spare room I never enter."

So the flow becomes: tag rooms → mark which you actually heat → the heat-map analysis literally sets the heating figure. *That's* the heat map doing real work, not decoration. Add one question per room: "**Do you use/heat this room?**" (yes / rarely).

⚠ Scope discipline (read this)

This is a **strong enhancement, not the core**. Priority order for tomorrow:

1.  **Core must work first:** EPC baseline + retrofit savings + room-level orientation advice.
2.  **Then add** the lifestyle sliders (Step 2-3) — a handful of dropdowns × multipliers, ~1 hour.
3.  **Only if time:** the per-room heat-map tie-in (Step 4) — lovely, but don't let it block the core.

Build it as **sliders that visibly move the range**. Even the simple version (Steps 2-3) already demonstrates "the EPC assumes; we personalise," which is the whole point. Keep every number a transparent, tweakable constant — that transparency *is* your credibility.
